

Executive Summary

- Motivation: Processors are present in everyday activities within computing systems.
- Problem: We need to understand the processor operation and design to propose future paradigms.
- Overview:
 - Computer definitions
 - Architecture models
 - ARM Instructions.
- Conclusion: We can start building a complex processor using design principles and fundamental building blocks.

Introduction

Computer Architecture

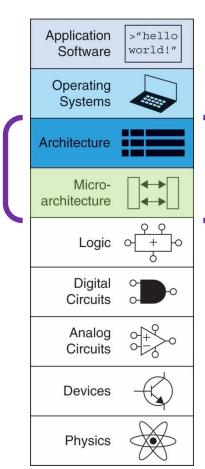

Instructions

Conclusion

Moving Towards the Abstraction Levels

- We have covered the lower levels on the previous lectures.
 - From bits to logic circuits (combinational and sequential).
- New domain:
 - Architecture: programmer's view of computer
 - Defined by instructions and operand locations
 - Microarchitecture: how to implement an architecture in hardware (more in later lectures).

Who is he?

Who is he?

• Why?

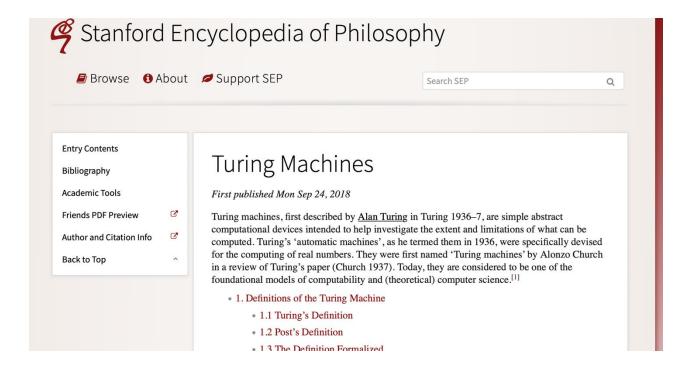

ON COMPUTABLE NUMBERS, WITH AN APPLICATION TO THE ENTSCHEIDUNGSPROBLEM

By A. M. Turing.

[Received 28 May, 1936.—Read 12 November, 1936.]

So, given some Turing machine T which is in state q_i scanning the symbol S_j its ID is given by Pq_iS_jQ where P and Q are the finite words to the left and right hand side of the square containing the symbol S_i . Figure 1 gives a visual representation of an ID of some Turing machine T in state q_i scanning the tape.

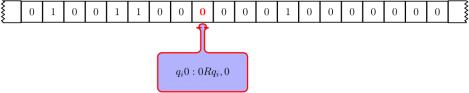

FIGURE 1: A complete configuration of some Turing machine T

The notation thus allows us to capture the developing behavior of the machine and its tape through its consecutive IDs. Figure 2 gives the first few consecutive IDs of $T_{\rm Simple}$ using a graphical representation.

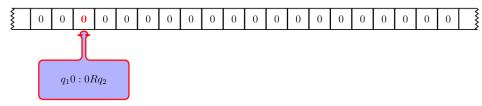

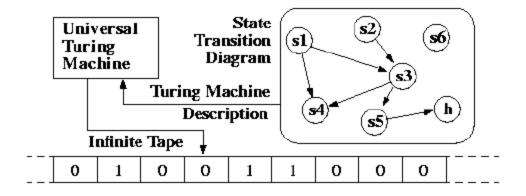

Figure 2: The dynamics of T_{Simple} graphical representation

11

1. Data processing

Multiple types of data and processing requirements.

2. Data storage

- Short-term
- Long-term

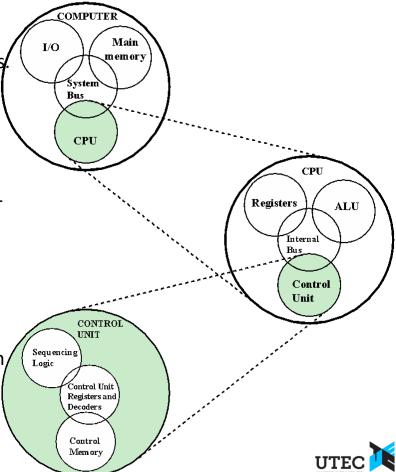

3. Data movement

 Input-output (I/O): when data are received from or delivered to a device (peripheral) that is directly connected to the computer

 Data communications: when data are moved over longer distances, to or from a remote device

4. Control

 A control unit manages the computer's resources in response to commands (instructions).

ARM Architecture

- Developed in the 1980's by Advanced RISC Machines now called ARM Holdings
- Nearly 10 billion ARM processors sold/year
- Almost all cell phones and tablets have multiple ARM processors
- Over 75% of humans use products with an ARM processor
- Used in servers, cameras, robots, cars, pinball machines, etc.

Once you've learned one architecture, it's easier to learn a different one 😊

Outline

Introduction

Computer Architecture

Instructions

Conclusion

Computer Architecture Models

Von Neumann:

- Single area of memory for program instructions and the data.
- Easier for circuit designers.

Harvard:

- Complete separation of code and data memory regions.
- Rarely used in modern computers.

Processor Control unit Instruction memory ALU Processor I/O device I/O device Data memory

Processor

unit

Registers

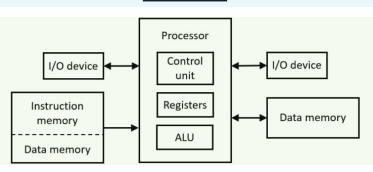

Memory

I/O device

I/O device

Modified Harvard:

- Some degree of separation between program instructions and data.
- Modern processors.

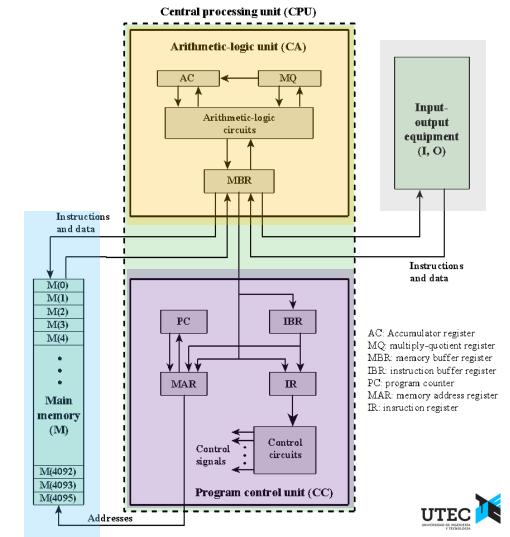

Von Neumann Model

 Proposed by [Burks, Goldstein and von Neumann, 1946] in "Preliminary discussion of the logical design of an electronic computing instrument"

5 parts:

- 1. Memory
- **Processing Unit**
- Input
- Output
- **Control Unit**
- **Bottleneck:** total time for access data can be higher than time for working in the actual program.

Memory stores:

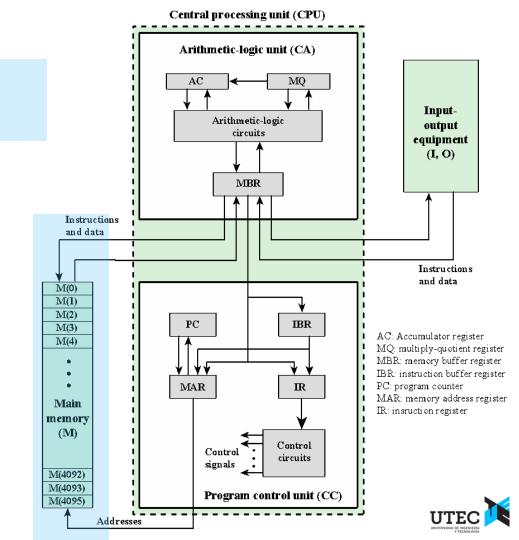

- 1) Data
- 2) Programs (instructions)

- Both are represented as bits
- Processor receives bits, control (FSM) determines if it is data or program.

Memory

17

- The memory stores
 - Data
 - Programs
- The memory contains bits
 - Bits are grouped into bytes (8 bits) and words (e.g., 8, 16, 32 bits)
- How the bits are accessed determines the addressability
 - E.g., word-addressable
 - E.g., 8-bit addressable (or byte-addressable)
- The total number of addresses is the address space
 - In ARM, the address space is 2³²
 - 32-bit addresses
 - In x86-64, the address space is (up to) 2⁴⁸
 - 48-bit addresses

Accessing Memory

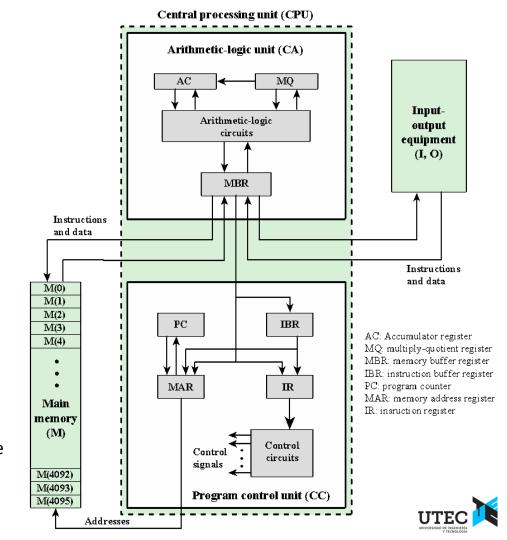

- There are two ways of accessing memory
 - Reading or loading
 - Writing or storing
- Two registers are necessary to access memory
 - Memory Address Register (MAR)
 - Memory Data Register (MDR)

To read

- Step 1: Load the MAR with the address
- Step 2: Data is placed in MDR

To write

- Step 1: Load the MAR with the address and the MDR with the data
- Step 2: Activate Write Enable signal

Word-Addressable Memory

- Each data word has a unique address
 - In ARM, a unique address for each 32-bit data word

Word	Data AF	RM memory
Address	•	•
	•	
00000003	D1617A1C	Word 3
00000002	13C81755	Word 2
00000001	F2F1F0F7	Word 1
00000000	8 9 A B C D E F	Word 0

Byte-Addressable Memory

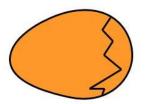

- Each byte has a unique address
 - Actually, ARM is byte-addressable

Byte Address	Data AR		M memory		
of the Word	-				
:	-				
000000C	D 1	61	7 A	1 C	Word 3
80000008	13	C 8	17	5 5	Word 2
00000004	F 2	F 1	F 0	F 7	Word 1
00000000	How are these four bytes addressed?			Word 0	

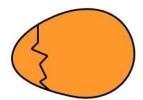

Big Endian vs Little Endian

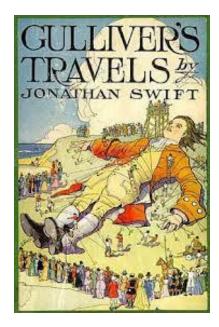

- Jonathan Swift's Gulliver's Travels
 - Little Endians broke their eggs on the little end of the egg
 - Big Endians broke their eggs on the big end of the egg

BIG ENDIAN - The way people always broke their eggs in the Lilliput land

LITTLE ENDIAN - The way the king then ordered the people to break their eggs

- How to number bytes within a word?
 - Little-endian: byte numbers start at the little (least significant) end
 - Big-endian: byte numbers start at the big (most significant) end

Big Endian vs Little Endian

Big Endian

Little Endian

Byte Address

Word Address

Byte Address

It doesn't really matter which addressing type used - except when two systems

share data

С	D	Е	F	С
8	9	А	В	8
4	5	6	7	4
0	1	2	3	0

F	Е	D	С
В	Α	9	8
7	6	5	4
3	2	1	0

MSB

LSB

MSB

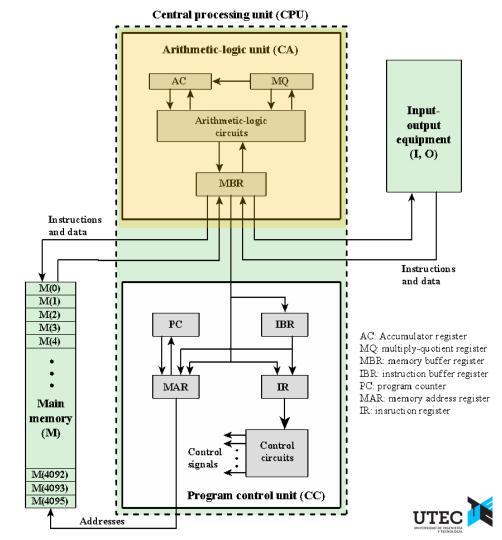

LSB

(Least Significant Byte)

Processing Unit

- The processing unit can consist of many functional units
- We start with a simple Arithmetic and Logic Unit (ALU), which executes computations
 - ARM: add, sub, mult, and, nor, ...
- The ALU processes quantities that are referred to as words
 - Word length In ARM it is 32 bits
- Temporary storage: Registers
 - E.g., to calculate (A+B)*C, the intermediate result of A+B is stored in a register

Registers

• **Memory** is big but slow

Registers

- Registers are faster than memory
- Ensure fast access to operands
- Typically one register contains one word

Register set or file

- ARM has 16 registers
- Each register is 32 bits
- ARM is called a "32-bit architecture" because it operates on 32-bit data

Name	Use
R0	Argument / return value / temporary variable
R1-R3 Argument / temporary variables	
R4-R11	Saved variables
R12	Temporary variable
R13 (SP)	Stack Pointer
R14 (LR)	Link Register
R15 (PC)	Program Counter

Register Set

Registers naming:

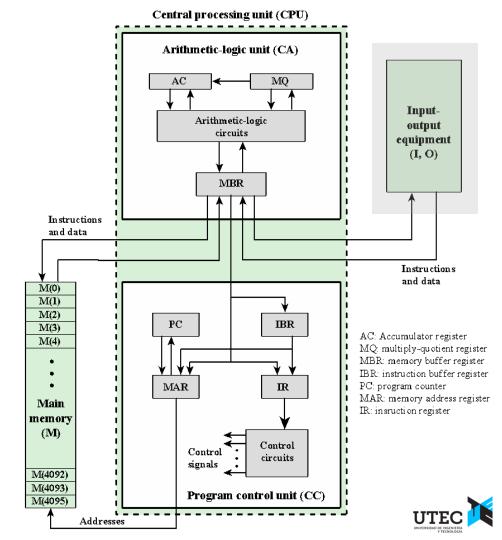

- R before number, all capitals
- **E.g.:** "R0" or "register zero" or "register R0"
- Used for specific purposes:
 - Saved registers: R4-R11 hold variables
 - Temporary registers: R0-R3 and R12, hold intermediate values
 - Discuss others later

Name	Use
R0	Argument / return value / temporary variable
R1-R3	Argument / temporary variables
R4-R11	Saved variables
R12	Temporary variable
R13 (SP)	Stack Pointer
R14 (LR)	Link Register
R15 (PC)	Program Counter

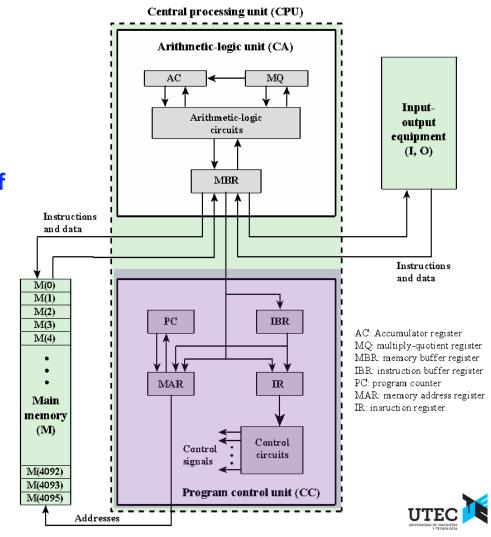

Input and Output

- Many devices can be used for input and output
- They are called peripherals
 - Input
 - Keyboard
 - Mouse
 - Scanner
 - Disks
 - Etc.
 - Output
 - Monitor
 - Printer
 - Disks
 - Etc.

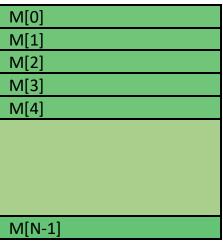

Control Unit

- The control unit is similar to the conductor of an orchestra
- It conducts the step-by-step process of executing (every instruction in) a program
- It keeps track of the instruction being executed with an instruction register (IR), which contains the instruction
- Another register contains the address of the next instruction to execute. It is called program counter (PC) or instruction pointer (IP)

Programmer Visible (Architectural) State

Memory array of storage locations indexed by an address

Registers

- given special names in the ISA (as opposed to addresses)
- general vs. special purpose

Program Counter

memory address of the current instruction

Instructions (and programs) specify how to transform the values of programmer visible state

Von Neumann Model

 Also called stored program computer (instructions in memory). It has two key properties:

1. Stored program

- Instructions stored in a linear memory array
- Memory is unified between instructions and data
 - The interpretation of a stored value depends on the control signals

2. Sequential instruction processing

- One instruction processed (fetched, executed, completed) at a time
- Program counter (instruction pointer) identifies the current instruction
- Program counter is advanced sequentially except for control transfer instructions

Introduction

Computer Architecture

Instructions

Conclusion

Instructions

- An instruction the most basic unit of computer processing
 - Instructions are words in the language of a computer
 - Instruction Set Architecture (ISA) is the vocabulary

- ARM is a Reduced Instruction Set Computer (RISC), with a small number of simple instructions
- Other architectures, such as Intel's x86, are Complex Instruction Set Computers (CISC)

Sequential Execution

- Instructions and data are stored in memory
 - Typically the instruction length is the word length
- Instructions: Commands in a computer's language
 - Assembly language: human-readable format of instructions
 - Machine language: computer-readable format (1's and 0's)
- The processor fetches instructions from memory sequentially (first one instruction, then the next one ...)
- The address of the current instruction is stored in the program counter (PC)
 - If word-addressable memory, the processor increments the PC by 1.
 - If byte-addressable memory, the processor increments the PC by the word length (4 in ARM)
 - E.g. OS sets the PC to 0x00400000 (start of a program), increment from this address value.

A Sample Program Stored in Memory

- A sample program
 - 4 instructions stored in consecutive words in memory
 - No need to understand the program now. We will get back to it

Program assembly

lw	\$t2,	32(\$0))
add	\$s0,	\$s1,	\$s2
addi	\$t0,	\$s3,	-12
sub	\$t0,	\$t3,	\$t5

Machine code

0x8C0A0020
0x02328020
0x2268FFF4
0x016D4022

Address	Instructions	Ī
0040000C	016D4022	
00400008	2 2 6 8 F F F 4	
00400004	02328020	
00400000	8 C O A O O 2 O	← P(
:	÷	
•	•	

Example 1: ADD Instruction

C Code

a = b + c;

ARM Assembly Code

ADD a, b, c

ADD: mnemonic – indicates operation to perform

• b, c: source operands

• a: destination operand

Example 2: SUB Instruction

Similar to addition - only mnemonic changes

C Code

a = b - c;

ARM assembly code

SUB a, b, c

- SUB: mnemonic
- b, c: source operands
- a: destination operand

Example 3: Multiple Instructions

More complex code handled by multiple ARM instructions

C Code

$$a = b + c - d;$$

ARM assembly code

```
a = b + c - d; ADD t, b, c ; t = b + c
               SUB a, t, d; a = t - d
```

Instructions with Registers

Revisit ADD instruction

C Code

$$a = b + c$$

ARM Assembly Code

;
$$R0 = a$$
, $R1 = b$, $R2 = c$
ADD $R0$, $R1$, $R2$

Operands: Constants and Immediates

- Many instructions can use constants or immediate operands
- For example: ADD and SUB
- value is immediately available from instruction

C Code

$$a = a + 4;$$

 $b = a - 12;$

ARM Assembly Code

Generating Constants

Generating small constants using move (MOV):

C Code

```
//int: 32-bit signed word
int a = 23;
int b = 0x45;
```

ARM Assembly Code

```
; R0 = a, R1 = b

MOV R0, #23

MOV R1, #0x45
```

Constant must have < 8 bits of precision

Note: MOV can also use 2 registers: MOV R7, R9

Generating Constants

Generate larger constants using move (MOV) and or (ORR):

C Code

```
int a = 0x7EDC8765;
```

ARM Assembly Code

```
# R0 = a

MOV R0, #0x7E000000

ORR R0, R0, #0xDC0000

ORR R0, R0, #0x8700

ORR R0, R0, #0x65
```

Ada Lovelace

- British mathematician, 1815-1852
- Wrote the first computer program
- Her program calculated the Bernoulli numbers on Charles Babbage's Analytical Engine
- She was a child of the poet Lord Byron

At her time, no high-level languages:

- e.g., C, Java, Python
- Written at higher level of abstraction

Types of Instructions and Programming Blocks

Three main types of instructions:

- 1. Data-processing Instructions
- 2. Branches
- 3. Memory

- High-level Constructs:
 - if/else statements
 - for loops
 - while loops
 - arrays
 - function calls

We study how to implement high-level programs using low-level definitions

How are These Instructions Executed?

- By using instructions we can speak the language of the computer
- Thus, we now know how to tell the computer to
 - Execute computations in the ALU by using, for instance, an addition
 - Access operands from memory by using the load word instruction
- But, how are these instructions executed on the computer?
 - The process of executing an instruction is called is the instruction cycle

More about instruction execution on next lecture.

Introduction

Computer Architecture

Instructions

Conclusion

Conclusions

- We introduced computer architecture models and detailed the relation between them.
- We detailed the Von Neuman model and its operation.
- We introduced the ARM instruction set architecture.
- We conclude that a processor operates through a defined set of instructions.

Homework

Read Chapter 6 from HH book. Instruction types and format.
